"An Immunofluorescent Study of Surface Antigens Induced by Human Adenovirus Type 12 in Various Systems of Cell Cultures"

Tbilisi, Soobshcheniya Akademii Nauk Gruzinskoy SSR, Vol 63, No 3, 1971, pp 713-716

Abstract: Adenovirus type 12, incubated with other cells, induces the formation of surface antigens in human amniotic A-1 cells and in hamster embryonic cells, though not in mouse embryonic cells. This is revealed by the indirect fluorescent antibody method: after addition of specific antibodies (obtained from hamsters repeatedly vaccinated with adenovirus) to the culture, fluorescent rings are formed on human amniotic and hamster embryonic cells. These antibodies interact neither with the virus or its antigen nor with control cultures. It is therefore concluded that the adenovirus induces the formation of specific antigens on the membrane of the host cell, which may endow the cell with antitumor immunity.

"Several Spectral Characteristics of Polystyrene Activated with Europium
Chelate"

Tbilisi, Soobshcheniya Akademii Nauk Gruzinskoy SSR, Vol 63, No 3, Sep 71,
pp 581-584

Abstract: The spectral characteristics of Eu^{3+} chelates have been investigated by a number of authors both in methylmetacrylate and in alcohol solutions. In this article the authors investigate samples of polystyrene doped with 0.02-2 Wt % europium benzoyl acetate; the samples are 15 mm in diameter and 2 mm thick. They find that such a material exhibits a strong absorption in the region of 3000-4000 Å and the material of the base that is, polystyrene has strong absorption bands in the ultraviolet band of the spectrum; however, it is fully transparent from 3000 Å and up to 1.1 μ. The luminescence and absorption spectra are graphically illustrated. The authors find that polystyrene is a successful base for europium benzoyl acetate. The article contains 3 illustrations and 8 bibliographic entries.

"Preparation of Initial Data for Stochastic Prognosis Systems"

V sb. Neurobionika (Neurobionics--collection of works), Kiev, 1970, pp 236-240 (from BZh-Matematika, No 11, Nov 71, Abstract No 11V856)

Translation: A mathematical model is considered for accommodation of the initial data in the memory of a stochastic prognosis system. A system of medical diagnosis is taken as an example. The memory of the system is modeled by a finite graph G in which each vertex corresponds to some state of the patient and a set of treatment methods which are used, two vertices being connected by an arc if and only if a transition is possible from a state corresponding to one vertex into a state corresponding to another. The procedure for calculating the statistical characteristics and transitions from state to state is presented. Digital computer programmed realization is based on construction of a vector whose components are graph vertices reflecting the course of an illness of a given patient. V. Mikheyev.

Translation: The paper deals with a mathematical model for accommodation of initial information in the memory of a stochastic prognosis system as illustrated by a medical diagnosis system. The memory of the prognosis system is modeled by a finite graph G, each of whose vertices is put into a one-to-one correspondence with some state of the patient and treatment complex. Two vertices are joined when and only when a transition is possible from the state corresponding to one vertex to that corresponding to the other. A procedure is given for calculating the statistical characteristics and the transitions from state to state. The digital computer program realization is based on construction of a vector whose components are graph vertices which map the course of the illness for the given patient.

"On a Model for Predicting the Flow of a Pathological Process in an Organism"

V sb. Neurobionika (Neurobionics--collection of works), Kiev, 1970, pp 241-243 (from RZh-Kibernetika, No 11, Nov 71, Abstract No 11V854)

Translation: The following problem is considered.

Let a given specific pathological process be characterized by symptoms M_i from a set M , where $0 < i \leq n$. Any combination of symptoms from M is called a state of the organism. These states are given on the set A , and let A_i be the elements of this set.
Then

$$I = \sum_{i=1}^n C_i$$

USSR

VARENIN, Yu. R., SOBOLEVA, E. N., Neyrobionika, Kiev, 1970, pp 241-243

The entire pathological process is broken up into k periods. Each period is designated by $k, 1 < r < k$. Then A_{jk_r} will characterize the j -th state in the k_r -th period. In order to predict the most probable nature of development of the pathological process, it is necessary to find the maximum probability of the transition $P_{\max A_{jk_r}}$ to $A_{j'r_{r+1}}$, where j' may be equated with j and designates a state different from j . "Experimental Study of Concentration Profiles in Ion Exchange
Membranes"

Moscow, Zhurnal Fizicheskoy Khimii, Vol 44, No 11, Nov 70, pp
2952-2954

Abstract: The article demonstrates the possibility of using
x-ray spectrum local analysis with the aid of an electron probe
for the study of concentration profiles in ion exchange mem-
branes. The distribution of Cu^{+2} , Ca^{+2} , Na^{+} ions in a hetero-
geneous (MK-40) and homogeneous (MK-100) membrane was studied.
Concentration profiles were obtained during ion transfer in a
constant electric field. Stationary profiles are given for Cu^{+2}
ions in an MK-40 membrane and Ca^{+2} ions in an MK-100 membrane.

Novosibirsk, Izvestiya Sibirskogo Otdeleniya AN SSSR, Seriya Khimicheskikh Nauk, Vyp. 6, No 14 (179), Nov 70, pp 8-13

Abstract: The authors study polarization on strongly ionized cation-exchange and anion-exchange membranes in solutions with various characteristics at concentrations of less than 0.1 N. The cation-exchange specimens were heterogeneous membranes based on KU-2 and various binders (polyethylene, polyvinyl chloride, polyfluoroethylene copolymer 42 L), and also homogeneous membranes produced by both chemical and radiation grafting of sulfogroups (MK-100, FK₃, MPFK-26). The anion-exchange membranes were based on strongly basic AV-17 resin and polyethylene binder. Polarization of these membranes was studied in NaCl, NaOH and HCl solutions. It was found that polarization characteristics for all investigated membranes are analogous regardless of the nature of the solution. The limiting currents on cation-exchange membranes in HCl

and on anion-exchange membranes in NaOH are lower than the theoretically calculated values by a factor of 2-3. The schlieren method is used to show that intense agitation of the solution takes place at the surface of the membrane with currents greater than the limiting value, this action being more pronounced for cation-exchange membranes.

Electrolytes"

Novosibirsk, Izvestiya Sibirskogo Otdeleniya AN SSSR, Seriya Khimicheskikh
Nauk, Vyp. 6, No 14 (179), Nov 70, pp 13-18

Abstract: The behavior of anion-exchange membranes during passage of direct current is studied as a basis for improving the process of electro dialysis. The study was based on heterogeneous and homogeneous ion-exchange films with various concentrations of strongly basic and weakly basic groups. The behavior of the ion-exchange membrane during passage of current was determined from the change in resistance of the membrane-solution system and from polarization measurements. For some membranes, a study was made of the change of pH of the solution as a function of the distance to the diaphragm at currents larger than the limiting value. The hydrodynamic conditions in the layer near the membrane were also studied as a function of the nature of the anion-exchange membranes. The schlieren method was used for this purpose. Polarization of the membranes was studied in sodium chloride and hydrochloric acid

1/2

USSR

PEVNITSKAYA, M. V., et al, Izvestiya Sibirskogo Otdeleniya AN SSSR, Seriya Khimicheskikh Nauk, Vyp. 6, No 14 (179), Nov 70, pp 13-18

solutions. It was found that the experimentally determined limiting currents for weakly basic membranes agree with theoretical calculations only for acids. In neutral solutions, the experimental values are lower than those calculated. Regardless of the type of membrane in NaOH solutions, the experimentally found currents are generally lower than the theoretical values by a factor of 2-3. The over-voltage at twice the limiting current is 2-5 volts higher than for cation-exchange membranes. This is apparently due to interaction between the membrane material and the electrolyte. If the logarithm of limiting current is plotted against the logarithm of concentration, the resultant graphs can be divided into two segments with slopes of 1.31-1.33 and 0.9 respectively. The values of the limiting current in the first region agree with theoretical data, while those in the second region are too high.

"Electroconductivity of Ion-Exchange Membranes and Nonhomogeneity of Their Structures"

Novosibirsk, Izvestiya Sibirskogo Otdeleniya Akademii Nauk SSSR, Seriya Khimicheskikh Nauk, No 2 (214), Mar 73, pp 3-8

Abstract: Electroconductivity of a series of ion exchange membranes has been studied in relationship to the nature of ionogenic groups, the technology of preparation (homogeneous and heterogeneous), and complete exchange capacity, as well as the nature, concentration and temperature of the solution. It has been established that the conductivity of ion exchange resin is affected principally by the spacial distribution of fixed ionogenic groups and not so much by their quantity. The nature of the nonhomogeneity of the ion exchange resin appears to have no effect on the conductivity.

ABSTRACT. IT IS KNOWN THAT HIGH MOLECULAR WEIGHT PRODUCTS FORMED DURING PROTEOLYTIC DEGRADATION OF FIBRINOGEN, INHIBIT THE FIBRIN MONOMER POLYMERIZATION. THE EXISTENCE OF COMPLEMENTARY STRUCTURES CHARACTERISTIC FOR THE SPECIFIC POLYMERIZATION CENTERS IN THESE FRAGMENTS MAY BE POSTULATED. HIGH MOLECULAR WEIGHT PRODUCTS, APPEARING DURING DEGRADATION OF FIBRINOGEN MOLECULE BY LOW CONCENTRATIONS OF TRYPSIN (ENZYME SUBSTRATE RATIO 1:2500 BY WEIGHT) WERE STUDIED. THEY WERE SEPARATED FROM TRYPTIC HYDROLYZATE OF FIBRINOGEN BY GEL FILTRATION ON SEPHADEX G 150. IT WAS SHOWN THAT DURING HYDROLYSIS LASTING FOR 120 HOURS AND MORE THESE PRODUCTS WERE GREATLY CHANGED IN THEIR ANTIPOLYMERIZING ACTIVITY, BEHAVIOUR IN GEL FILTRATION AND POLYACRYLAMIDE GEL ELECTROPHORESIS AND N TERMINAL AMINO ACIDS AS WELL. THE MOST ACTIVE AND AT THE SAME TIME THE LEAST HETEROGENEOUS PRODUCTS WERE PRODUCED DURING THE PROLONG HYDROLYSIS OF FIBRINOGEN BY TRYPSIN.

"Study of the Velocity of Ultrasonic Propagation at Frequencies of 0.62-10 Mc in n-Hexane, n-Heptane, n-Octane, and Cyclohexane at Pressures up to 2500 Atm. and Temperatures up to 120°C"

Kiev, Ukrainskiy Fizicheskij Zhurnal; December, 1972; pp 2048-51

ABSTRACT: The paper describes the methods and results of studies on ultrasonic velocity propagation in n-hexane, n-heptane, n-octane, and cyclohexane within a frequency range of 0.62-10 Mc at pressures up to 2500 atm. and temperatures up to 120°C. It is shown that within the ranges of temperatures, pressures, and frequencies studied, sonic velocity dispersion is absent for all paraffins under study. For liquids in which the P-V-T relation is described by the Tait equation the dependence of $\frac{c^2 \rho^2}{\gamma}$ on the pressure is linear.

At pressures from 1 to 2000 atm. a regularity is observed in the disposition of the sonic velocity polytherms: the greater the energy of collective interaction, the greater the ultrasonic propagation velocity within the ranges of temperature and pressure studied. At pressures of 2000 atm. and higher the differences in ultrasonic velocities for all the liquids studied are within the limits of experimental error (less than 0.2%).

Using the Bridgman model on two mechanisms of the effect of pressure on the structure of the liquids, the authors came to the conclusion that with an increase in pressure the packing varies in a similar manner for n-hexane, n-heptane, and n-octane particles and at 2000-2500 atm. is similar to the packing of cyclohexane molecules.

"Some Possibilities of Using Optoelectronic Switches in Microelectronic Circuits"

Moscow, Pribery i Sistemy Upravleniya, No 2, 1972, pp 45-46

Abstract: The OER-2 optoelectronic converters -- a film photoresistor and gallium phosphide light diode couple mounted in the TC-5 housing -- were described previously [F. I. Vergunas, et al., Pribery i sistemy upravleniya, No 1, 1972]. In the present article a study is made of the possibilities of using OER-2 in phase automatic frequency control circuits, in automatic phase control systems and as a controllable divider. The operating characteristics of the OER-2 in the various applications are described. Some advantages of the three mentioned circuits using the OER-2 include the following, respectively: 1) the filter band width switching circuit using the OER-2 is very simple, does not require regulation and has an intake of no more than 10-20 milliwatts; 2) absence of a galvanic coupling between the control voltage from the discriminator and the signal the phase of which must be reversed in the automatic phase control system; 3) application of a photoresistor as the controllable element permits a divider to be obtained which is linear in a broad range of operating voltages 1/2

"Cis-Trans-Isomerization of Cinnamoyl- α -Chymotrypsin Under the Effect of Light,
and Modeling of Molecular Mechanisms of Optical Reception"

Moscow, Doklady Akademii Nauk SSSR, Vol 193, No 4, Aug 70, pp 932-935

Abstract: Only recently has the experimental basis for representing the mechanism of the primary act of photoreception been established. Modeling of this process is of extreme importance, because it is easier to study and comprehend the overall physical and chemical aspects of the molecular mechanisms of light in biological systems. In addition modeling the photoreception mechanism, as an element of chemical bionics, may lead to the creation of artificial, light-sensitive systems operating according to the principle of the visual organs of animals. The absorption of light quanta in the photoreceptor cells of the retina affects many light-sensitive pigments. All the pigments contain as a chromophoric group an 11-cis-retinal group, bonded in the form of a Schiff's base to the NH₂-group of specific albumins. The first stage of the mechanism of vision includes the following processes: 1) trans-photostereoisomerization of the 11-cis-retinal

1/2

USSR

BEREZIN, I. V., et al, Doklady Akademii Nauk SSSR, Vol 193, No 4, Aug 70, pp 932-935

group, 2) the dark process, which is a chain of conformational changes of apoprotein, with the last reaction a hydrolysis step leading to the formation of free all-transretinal and opsin; 3) the further course of the transformation process of light consists of signal amplification, (which may be enzymatic). These processes were studied with certain chymotrypsin derivatives proposed as models. Deacylation of cis-cinnamoyl- α -chymotrypsin, synthesized by the authors, does not take place even at the optimum pH for the catalytic action of chymotrypsin. Rather, the compound has to be converted into the trans-isomer by irradiation with UV light, which is rapidly deacylated into trans-cinnamic acid and the free enzyme. The enzymatic photo-initiation process leads to an amplification of the primary light signal as a result of the accumulation of reaction products.

"Experimental Determination of the Thermal Conductivity of Sodium Vapor"

Moscow, Teplofizika Vysokikh Temperatur, Vol 11, No 2, Mar/Apr 73, pp
422-423

Abstract: A previous paper (Vargafnik, N. B., Voshchinin, A. A., Teplo-
fizika Vysokikh Temperatur, Vol 5, No 5, 1967) gave the results of mea-
surements of the thermal conductivity of sodium vapor by the method of
coaxial cylinders. In these experiments, the fraction of radiant heat
transfer was 20-40%. To reduce the percentage of radiation, the authors
of this paper made a new installation with a working gap of 0.2 mm instead
of the 0.6 mm used in the previous research. The measurements were made
at 1095 K and 2000-50000 N/m². In spite of the relatively low pressures,
the concentration of diatomic molecules varied considerably (from 1 to 10%).
The thermal effects of the reaction were considerable, affecting both the
thermal conductivity and the effective heat capacity. The results of the
experiments are tabulated. The experimental error is about 6%. It is

found that at about 1100 K (the principal isotherm) the ratio of thermal
conductivities of sodium vapor at 50000 and 10000 N/m² is about 1.30,
which agrees well with data in the literature obtained by another method.

"Experimental Study of the Coefficient of the Thermal Conductivity of the Vapors of Cesium"

Moscow, Teplofizika Vysokikh Temperatur, Vol 10, No 1, Jan-Feb 1972, pp 57-65

Abstract: The authors present the results of measuring the coefficient of the thermal conductivity of cesium vapors using the method of coaxial cylinders in the 680-1080°K temperature interval and at pressures of 0.001-1.3 bar. Two series of experiments on the thermal conductivity of cesium vapors were performed. The results show that the values of the criteria $Le=0.30$ and $Le=0.32$ indicate the closeness of the results for both sets of experiments with respect to the effect of the dissociation reaction on thermal conductivity. The discrepantcy in λ/λ_1 for the experimental points of both series at a given cp/c_{p1} is 2 percent. The resulting experimental data are generalized on the basis of equations proposed for the thermal conductivity of dissociating gases. Original article: seven formulas, three tables, five figures, and 15 bibliographic entries.

"Transformations of the Polarized Basis in Statistical Modeling of the Dispersion Characteristics of Objects"

Moscow, Radiotekhnika i Elektronika, Vol 17, No 4, Apr 72, pp 730-736

Abstract: A statistical model of a radar target is defined as an adequate statistical description of the dispersion operator of the target defined in some polarization basis as a random function of coordinates and time. In the general case, the statistical model of an object is a multidimensional law of the probability distribution of its dispersion operator. One of the most widely used methods for synthesizing such a model is statistical modeling of the dispersion characteristics of the object. In the general case, the polarization basis of the radar station may not coincide with that of the dispersion operator on the initial modeling stage. This paper examines a procedure for transformation of the polarization basis as part of a general algorithm for statistical modeling of dispersion characteristics. Principles are defined which govern the change in the dispersion operator of an object due to transformations of this type.

"Radar Reflector for Polarization Measurements"

Leningrad, Izvestiya VUZ -- Priborostroyeniye, No. 8, 1970, pp 10-14

Abstract: The authors describe experiments conducted on standard reflectors widely used for measuring the dispersion characteristics of radar targets and for tuning and calibrating radar equipment. Knowing the geometrical dimensions of these reflectors, the researcher can analytically determine their effective dispersion area. The reflector used in these experiments was of the Van Atta type, a grid of individual elements interconnected by pairs of equally long lines. The polarization characteristics of this reflector and the extent of their control -- in particular, verification of the possibility of imitating, through the use of the reflector, radar targets of various types -- were investigated. The experimental reflector consisted of 16 linearly polarized elements, and the antenna elements were optimal overlapping rectangular horns of 135 by 90 mm, arranged on a metallic panel covered on the horn side by radiation-absorbent material. A frequency of 9370 MHz was used, and the equipment was standard transceiver equipment used in polarization measurements.

and ultraviolet regions of the spectrum. The experimental results are compared with calculations for pure carbon dioxide. Satisfactory agreement is observed in the region below 3500 Å (i. e., at this wavelength and shorter). In the long-wave region where the Swan C₂ molecular system begins to make itself felt, the theoretical curve lies much lower than the experimental data, which fact is attributed to the composition of the gas assumed for the initial data of the calculations.

"Emittance of Carbon Dioxide Plasma at Temperatures of 7000-9000°K in the Spectral Interval of 2100-10,000 Å"

Moscow, *Teplofizika Vysokikh Temperatur*, Vol 10, No 4, Jul/Aug 72, pp 732-737

Abstract: The emittance distribution of a carbon dioxide plasma is determined at atmospheric pressure over a broad spectral interval of 2100-10,000 Å at temperatures of 7000, 8000, and 9000°K. The results are given in the form of graphs. The distributions found for intensities at wavelengths longer than 6000 Å show characteristic differences from the distributions at shorter wavelengths -- at 7000°K the line emission is very weak and the principal contribution is from molecular systems, one of the strongest being the Swan C₂ system. At 9000°K there is a sharp increase in the emission contribution from the line spectrum. At wavelengths shorter than 5650 Å there are breaks in the curve for intensity as a function of wavelength on the strongest lines in the visible

Moscow, Zhurnal Mikrobiologii, Epidemiologii i Immunobiologii, No 5, 1973, pp 83-87

Abstract: A total of 29 virus strains - 12 tickborne encephalitis and 17 Uukuniemi -- were isolated from about 14,000 adult ticks collected from 1969 to 1971 in 4 of the 5 ecological and faunal regions of Lithuania. (Two Uukuniemi virus strains isolated in 1970 from Ixodes ricinus ticks were the first strains of this virus to be found in the USSR). Tickborne encephalitis virus strains were isolated both from Ix. ricinus (11) and from Ix. persulcatus (1), while Uukuniemi virus strains were isolated only from Ix. ricinus. These arboviruses were isolated almost 3 times as often from ticks collected in June as from those collected in August. The number of individuals immune to Uukuniemi virus in the regions where it was isolated was 4.8 times greater
1/2

"Changes in the Properties of Antibodies During Immune Response of Rabbits to Inoculation With West Nile Virus. The Characteristics of Homologous and Heterologous Activity of Immunoglobulins in Hemagglutination-Inhibition Tests"

Moscow, Voprosy Virusologii, No 5, Sep/Oct 72, pp 540-544

Abstract: Rabbits were immunized with various doses of live virus and virus inactivated with formaline and absorbed on aluminum hydroxide, and blood samples were collected at 2-5 day intervals for 7 weeks. The physical and chemical properties of the antibodies were determined by the 2-mercaptoethanol test and by gel-filtration through Sephadex G-200. It was established that changes observed in antibody specificity were not due to a substitution of IgM antibodies with the IgG type, but that they were conditioned by the dose of the virus, its physical condition (live or inactivated and absorbed); and by the time factor. IgM and IgG antihemagglutinins reacting only with homologous virus were identified. Type 19S antibodies interacting with West Nile, Ntaya, St. Louis, and Japanese encephalitis viruses and those interacting with West Nile, Ntaya, St. Louis, Japanese encephalitis, and Ilheus viruses were described. A functional heterogeneity of the antihemagglutinins in IgM and Ig G immunoglobulins is postulated.

"Use of the Color Test for Titration of Antibodies to West Nile Fever Virus in Microvolumes of Serum"

Moscow, Voprosy Virusologii, No 4, Jul/Aug 70, pp 500-502

Abstract: A modification of the Huang color test was used to determine antibodies to West Nile fever virus (strain B-956) in sera (volumes of 0.6 ml and 0.075 ml) from immunized rabbits. Neutralization of cytopathic activity was studied simultaneously. The results of titrating the antibodies were very close in all cases, indicating that the color test is as sensitive as other available methods. It is suggested that the color test be used for research on other arboviruses, in view of the good results obtained in experiments with St. Louis encephalitis virus and the cytopathic variant of Tahyna virus.

"Synthesis of Complementary Virus-Induced RNA in Two Strains of Newcastle Disease Virus"

Moscow, Voprosy Virusologii, No 6, Nov/Dec 71, pp 693-697

Abstract: In chick embryo cell cultures inoculated with the Beaudette strain of Newcastle disease virus, virus-induced RNA accumulates about twice as fast as in cells infected with the Tomilinskiy strain. The distribution of RNA into sedimentation strata and the ratio of "plus" to "minus" chains are similar in both strains. Upon fractionation of the cell extract, the virus-induced RNA is distributed between the polyribosome and the postribosome zones of the sucrose density gradient in an almost identical manner for both strains. After simultaneous inoculation of one culture with both strains, the rate of RNA synthesis is close to that observed in infection with the Tomilinskiy strain. The results indicate that a regulatory mechanism exists at the level of RNA transcription. Possibly, a regulating factor is present in cells infected with the Tomilinskiy strain. In double infection, this factor inhibits RNA synthesis induced by the Beaudette strain.

"Metastable Phases in Binary Nickel Alloys Crystallized at Rapid Cooling Rates"

Sverdlovsk, Fizika Metallov i Metallovedeniye, Vol 33, No 2, Feb 72, pp 335-338

Abstract: The phase composition of Ni-Mo, Ni-Ta, Ni-Nb, Ni-Ti, and Ni-Zr alloys was investigated at an alloy cooling rate of 10^7 - 10^8 deg/sec. These cooling rates were achieved by blowing the cupel of the melt (2000°C) with a jet of compressed helium onto the surface of the copper cylinder which rotated at the rate of 8000 rpm. This cooling method produced films 0.01-0.02 mm thick. For each of the alloys the authors determined the equilibrium solubility at the eutectic temperature, eutectic point and region of homogeneity for the high-temperature phase, the maximum solubility, and the maximum supersaturation of the solid solution. It was determined that the rapid cooling rates produce a metastable phase with the simplest grain structure which is formed as the result of the increased rate of nucleation and subsequent growth. Two figures, 3 tables, 8 bibliographic references.

Ordzhonikidze, Izvestiya vysshikh uchebnykh zavedeniy, Tsvetnaya
metallurgiya, No 2, 1972, pp 92-95

Abstract: This study concerns certain crystallization characteristics of Ni-Cr and Ni-V alloys at cooling rates of 10^7 to 10^8 deg/sec effected by blowing out droplets of the melt (with compressed helium) onto the surface of a copper cylinder rotating at 8000 rpm. This method of cooling produces 0.01-0.03-mm films for x-ray diffraction and metallographic analyses to determine their phase compositions and crystal lattice periods. The data on variations of the crystal lattice periods, microhardness, and microstructure values of both alloys are reflected in curves showing them as a function of composition. "Thermal Expansion of Al-Mo and Al-Zr Alloys, Produced With High Cooling Rates"

Sverdlovsk, Fizika Metallov i Metallovedeniye, Vol 30, No 2, Aug 70, pp 443-445

Abstract: With cooling rates on the order of 10^4 - 10^6 /sec from the liquid state, a significant expansion of the area of the solid solution is noted in alloys of aluminum with transition metals. This process is accompanied by the appearance of metastable phases and changes in a number of physical properties of the solid solution. One of the most important peculiarities of the metastable solid solutions is their high temperature stability. This work presents a study of the changes in the coefficient of linear expansion of Al-Mo and Al-Zr alloys in the 23-450° interval. Foil specimens 0.09-0.1 mm thick were produced by cooling a drop of the melt on a rotating copper drum.

"Electrochemically Generated Free Radicals. 6. The Reduction Mechanism of Certain Organophosphorus Compounds, and the Electron Paramagnetic Resonance Spectra of the Anion Radicals Formed"

Moscow, Izvestiya Akademii Nauk SSR, Seriya Khimicheskaya, No 4, 71, pp 770-776

Abstract: A series of organophosphorus compounds was studied in connection with their electrochemical reduction, using several methods. The electron paramagnetic method was applied in the case of electrochemically generated anion radicals of triphenylphosphine, its oxides, and the diethyl ester of β -styrylphosphonic acid.

Graphical data accompanying the paper include classical and commutated polarograms for the various compounds, and electron paramagnetic spectra for free radicals; numerical electrochemical data are given for nine organophosphorus compounds tested.

ABSTRACT/EXTRACT--(U) GP-0- ABSTRACT. THE EFFECT OF FAST NEUTRON IRRADIATION ON THE ANGULAR DISTRIBUTION OF ANNIHILATION γ QUANTUM PAIRS IN CRYSTAL AND FUSED QUARTZ IS INVESTIGATED. IT IS FOUND THAT THE HALFWIDTH OF THE CORRELATION CURVES CORRESPONDS TO THE VARIATION OF THE QUARTZ DENSITY. FROM AN ANALYSIS OF VARIOUS POSITRON STATES IN QUARTZ PRECEDING ANNIHILATION AND ON BASIS OF THE EXPERIMENTAL DATA IT IS CONCLUDED THAT VARIATION OF THE HALF WIDTH IS DUE TO THE APPEARANCE IN THE CORRELATION CURVES OF A NARROW COMPONENT WHOSE INTENSITY DEPENDS ON THE RADIATION DOSE. THE NARROW COMPONENT IS DUE TO ANNIHILATION DECAY OF PARA POSITRONIUM ATOMS PRODUCED IN IRRADIATED QUARTZ.

"Call Signal Automation for a Personal Radio Call System"

Tr. nauch.-tekhn. konferentsiy Kaluzh. obl. sovet nauch.-tekhn. o-v (Works of Scientific and Technical Conferences. Kaluga Regional Council of Scientific and Technical Societies), Kaluga, 1970, pp 73-77 (from RZh-Radiotekhnika, No 6, Jun 71, Abstract No 6A196)

Translation: The paper describes the structure of a module in an automatic system for calling a certain subscriber by a combination of two frequencies out of eight, assuming a certain sequential order of frequencies. Call reliability is improved by multiple repetition of the signal. The principal component of the module is the subscriber identifier which is used for setting up different combinations of controlling signals corresponding to subscriber numbers. According to the signal given by the subscriber identifier, a call signal oscillator unit generates the call signal. The figures of merit are given for the circuits of various elements in the module. Three illustrations. N. S.

"Concerning the Mechanism of Failure of Gunn Diodes"

Leningrad, Fizika i Tekhnika Poluprovodnikov, Vol 6, No 9, Sep 72, pp 1670-1676

Abstract: Devices based on the Gunn effect operate most effectively at high bias voltages; however, increasing the voltage causes breakdown of the device. At present there is no unanimous opinion on the mechanism of failure and degradation of Gunn diodes. In this paper the authors investigate coplanar Gunn diodes with plane-parallel and annular electrode configurations both with and without a silicon dioxide passivating coating. The diodes were tested in the pulse mode. It is shown that in accordance with previously available experimental data the failure of Gunn diodes takes place as a result of formation of a shorting channel between the contacts of the device. Information is obtained on the dynamics of the visible portion of the breakdown by means of motion picture photography of this process through an optical microscope. It is shown that silicon dioxide passivation of the

1/2

USSR

CHIGOGIDZE, Z. N. et al., Fizika i Tekhnika Poluprovodnikov, Vol 6, No 9, Sep 72, pp 1670-1676

active region has an appreciable effect on the nature of the visible portion of the breakdown and on the ratio of the breakdown voltage to the threshold voltage. A microscopic x-ray analysis is made of the composition of the contact regions and the channel on various stages of thermal breakdown. It is found that a transverse magnetic field affects the position of the shorting channels and the ratio of the breakdown voltage to the shorting voltage. A study is made of Gunn diode emission in the infrared region of the spectrum at voltages close to the breakdown voltage. It is concluded that the cause of failure of Gunn oscillators at high bias voltages is the formation of current strings caused by the development of an S-shaped current-voltage curve due to impact ionization when a strong field domain passes over the specimen. The authors thank M. S. Shur for discussing the results of the paper, and N. N. Mamatsashvili for taking part in the measurements.

"A Logic Threshold Device"

USSR Author's Certificate No 278751, Filed 5 Jun 69, Published 3 Dec 70
(from Referativnyy Zhurnal -- Avtomatika, Telemekhanika, i Vychislitel'naya
Tekhnika, No 8, 1971, Abstract No 8B134 P)

Translation: A logic threshold device is proposed which contains a diode-resistor adder and a discriminator made from a tunnel diode and a transistor. Their purpose is to increase the operational reliability of the device and to expand its logic capabilities. The discriminator contains supplementary photodiodes, and the adder contains electroluminescent diodes and a tunnel diode. The anode and cathode of the tunnel diode are joined to the anodes of the electroluminescent diodes and optically connected with the photodiodes of the discriminator, whose anodes, in turn, are connected via tunnel diodes to the bases of the transistors.

"Synthesis and Study of Properties Bis(organophosphinoxy)dibutoxy Titaniums"
Leningrad, Zhurnal Obshchey Khimii, Vol 40, No 7, Jul 70, pp 1560-1565

Abstract: The authors previously studied the synthesis of some bis(organophosphinoxy)dibutoxy titaniums by the condensation of tetrabutoxytitanium with phosphorus monoacids or acid mono chlorides. In the present article the authors report using an analogous method to obtain similar compounds containing a catecholoxy or methylene-o-carboranene group at the phosphorus. The synthesis of the former was through the corresponding acid mono chloride, the latter through 1,2-methylene-o-carboranephosphoric acid. The resistance of these and the previously synthesized compounds to thermo oxidative degradation was studied. It was found that thermo oxidative degradation is accompanied by loss of the organic part of the monomers. Given the same titanium framework, the comparative resistance to thermo oxidative degradation for similar compounds is determined by the stability of the organic phosphorus framework.

"Heat Conducting Organosilicon Materials"

Obmen opytom v radioprom-sti (Experience Pooling in the Radio Industry),
Vyp. 10, Moscow, 1970, pp 39-40 (from RZh-Radiotekhnika, No 2, Feb 71,
Abstract No 2V320)

Translation: The overall thermal conductivity of a given device may drop appreciably as a result of an increase in contact thermal resistance when there are air gaps between contacting surfaces. These resistances are reduced by using heat conducting pastes, those with an organosilicon base in particular. Among these are thixotropic pastes designed merely for filling gaps and not for cementing, and pastes of the "Elastosil" type which harden after application and may also act as cements or sealants. Data on these pastes are given. Three tables. N. S.

ABSTRACT/EXTRACT--(U) GP-0- ABSTRACT. INVESTIGATION OF THE TRANSIENT RESPONSE CHARACTERISTICS OF A NEW SERVO ELECTRIC MOTOR WHICH INVOLVES A COMBINATION OF AN ELECTROMECHANICAL ENERGY CONVERTER WITH WAVE TRANSMISSION. THE MOTOR IS CHARACTERIZED BY THE PRESENCE OF TWO MOMENTS: (1) THE MOMENT CREATED BY THE FORCES OF A ROTATING ELECTROMAGNETIC FIELD, AND (2) THE MOMENT ARISING AT THE OUTPUT TRANSMISSION SHAFT DUE TO THE CONVERSION OF WAVE DEFORMATION INTO SLOW ROTATION. THE ENERGY METHOD IS USED TO CALCULATE THE MOMENT OF INERTIA OF AN ELASTIC ROTOR DURING WAVE DEFORMATION. THE SYNCHRONOUS ELECTROMAGNETIC MOMENT AT THE STATOR SURFACE, WHICH CAUSES A DISPLACEMENT OF THE DEFORMATION WAVE, IS ALSO CALCULATED. EXPRESSIONS ARE OBTAINED FOR THE ELECTROMECHANICAL START UP TIME CONSTANTS OF REACTIVE WAVE MOTORS AND WAVE MOTORS WITH EXCITATION. EXPERIMENTAL RESULTS ARE OUTLINED, AND IT IS SHOWN THAT THE RESPONSE OF A WAVE MOTOR IS MUCH FASTER THAN THAT OF AN ASYNCHRONOUS ELECTRIC SERVO MOTOR WITH A HOLLOW ROTOR.

EFFECT OF TUNGSTEN ON THE LAVES PHASE STRUCTURE IN THE CO-NB-V SYSTEM
UDC 669.017.3

Article by K. V. Varli, N. P. Rykonoza, N. V. Orlina, Ya. S. Usanovskiy, M. S. Kozlov, Institute of Metallurgy, Department of X-ray Spectroscopy and Physics, Ural State University, Sverdlovsk, 1972, *Izv. Vsesoyuznogo Nauchno-Issledovatskogo Instituta Metallov*, No. 1, 1972, submitted 2 July 1971, pp. 115-117.

In the Co-Nb-V ternary system, the following crosssections were investigated: parallel to section 1A and passes through the middle of the region of homogeneity of the Laves phase (FeCo₂ type) from the Nb side; section 1B is parallel to section 1A and passes through the middle of the region of homogeneity of the Co₂Nb phase [1], that is, it is shifted toward higher Co content; section 2 -- Co₂Nb (right type) [1] -- Co₂Nb (right type) [2]; section 3 -- Co₂Nb (left type) [1] -- Co₂Nb (left type) [2]. The compositions of the investigated alloys are presented in Table 1.

"Structural and Phase Changes in Ferrite Steel During Heat Treatment"
Moscow, Izvestiya Vysshikh Uchebnykh Zavedeniy -- Chernaya Metallurgiya, No 9,
1970, pp 117-121

Abstract: A study was made of structural and phase changes in EP-503 ferrite steel containing 8% W during heat treatment. The tests were conducted 1) after forging with 960-840°C end temperature, with subsequent water and furnace cooling; and 2) after hardening at 1200°C with subsequent water cooling. The temperature interval of the Fe₂W phase precipitation and related changes in hardness, lattice period of solid solution, and electric resistance were determined. Microstructures of the steel after forging, hardening, and tempering under various conditions are presented, and results are given of metallographic analysis of the steel after hardening at 1200°C. The lattice period of a solid solution of forged samples at certain temperatures is smaller than that of hardened samples, owing to the precipitation of Fe₂W phase particles during forging. The variation of particle size and lattice periods of the Fe₂W phase with tempering temperature were determined.

Semenova, V. I. Electromagnetic wave reflection during oblique incidence on a moving ionization front. IYUZ Radiofiz., no. 5, 1972, 665-674.

An extensive theoretical analysis is given of the interaction of a monochromatic wave with a plasma boundary. The particular case considered is of inclined incidence of incoherent TE and TM waves upon a sharply defined boundary of a plasma half-space, where the plasma is generated by ionizing radiation acting on a neutral gas. For simplicity the incident pulse is assumed arbitrary narrow and the dielectric constant outside the plasma is taken to be unity. It is shown that when the E-field normal to plane of incidence, the spulation for the inclined incidence case is essentially the same as shown to generate two axial waves in addition to the transverse ones, at any given frequency of the incident waves. Formulas for the reflection and transmission of the latter are obtained and analyzed in terms of the idealized plasma parameter.

Kuznetsov, A. Ya., I. S. Varnasheva, A. A. Poplavskiy, and G. P. Zakhomirov. Destruction of reflective dielectric coatings by laser radiation. OMIP, no. 3, 1972, 39-42.

The resistance of reflective coatings to laser radiation was studied using zinc sulfide and magnesium fluoride coatings. The coatings were applied by thermal evaporation in a vacuum, and the reflection factor was R = 90% at $\lambda = 0.7 \mu$. The flux falling upon the specimen was controlled

"Formation of Nonmetallic Inclusions In the Deoxidation of Iron With Titanium"

Moscow, Izvestiya Uchebnykh Vysshikh Zavedeniy--Chernaya Metallurgiya, No 6, Jun 73, pp 53-56

Abstract: An iron rod 5.0-6.0 mm in diameter and 65 mm long was placed in a magnesite crucible and heated in a resistance furnace to 1570°C where titanium was added to the metal surface through a quartz tube. Melting was sustained from 5 to 15 min. after which the crucible was removed from the furnace and quenched in water. Titanium was added so that its distribution along the rod length was 0 to 0.3-1.5%. Oxygen and nitrogen content in the initial samples was equal, which made it possible to study the composition and nature of inclusions for the different concentrations of titanium, oxygen, and nitrogen in the iron. It was found that the primary products from reduction of iron with titanium are molten oxides of the type $n\text{FeO} \cdot m\text{TiO}_2$. According to the degree of increasing the ratio of Ti/O_2 , solid Ti_2O_3 and TiO are crystallized from the melt, and with high concentrations of nitrogen-- TiN (solid). Since solid crystals of inclusions of oxides and titanium nitride separate out on molten
